RE: Estimate of Wildlife Refuge Benefit from the Kern Fan Groundwater Storage Project for the Water Infrastructure Improvement for the Nation Program (WIIN)

Introduction

This technical memo outlines the data and methodological approach for calculating the economic benefits of Irvine Ranch Water District's (IRWD) and Rosedale Rio Bravo Water Storage District's (Rosedale) proposed Kern Fan Groundwater Storage Project in support of a feasibility study under the Water Infrastructure Improvements for the Nation Program (WIIN). This memo focuses specifically on estimating the value of water supplied to the Kern National Wildlife Refuge under the Kern Fan Project and updating all benefit results to reflect the Bureau of Reclamation's current 2.75% discount rate.

Overview

Table 1 shows all benefits identified for the Kern Fan Project. These benefits have been calculated using the current Bureau of Reclamation discount rate of 2.75%, as provided by the US Department of the Treasury.¹ Because future benefits are now discounted at a lower rate than applied initially, all project benefits increase slightly under the current calculations.²

Table 1 also includes the additional benefit of providing Level 4 water supplies to the Kern National Wildlife Refuge in the Central Valley, a total benefit of \$6.4 million.

Project benefits are expected to begin in 2026 and continue throughout the 50-year life of the project, through 2075. We calculate net present value at the project start in 2026. All benefits are calculated initially in 2015 dollars and subsequently inflated to 2018 dollars based on the Consumer Price Index reported by the California Department of Finance.³

Throughout this analysis we rely on work already produced for the Kern Fan Project to apply for funding under California's Water Storage Investment Program (WSIP).

¹ https://www.treasurydirect.gov/govt/rates/tcir/tcir_fy2020_opdirannual.htm#table4

² Previous calculations of Kern Fan project benefits were completed using a previous USBR discount rate of 2.88%.

³ <http://www.dof.ca.gov/Forecasting/Economics/Indicators/Inflation/>

Table 1. Summary of Benefit Estimates (2018 dollars)

Type of Benefit	NPV of Benefits (2.75%)
Water Supply Benefits—M&I	\$51.0
Water Supply Benefits—Agriculture	\$81.3
Water Supply Benefits--Groundwater	\$9.3
Environmental Benefits—Fish species recovery	\$38.6
Environmental Benefits—Incidental Wetland Habitat	\$165.2
Emergency Response—Extended drought	\$18.6
Emergency Response—Delta failure	\$30.7
Agricultural Benefits	\$26.4
Water Supply Benefits—Wildlife Refuge Level 4	\$6.4
Total Benefits	\$427.5

Benefits

Water Supply—Wildlife Refuge Level 4 Supplies

The project will supply Level 4 water supplies to wildlife refuges in below normal, dry, and critical water years. MBK Engineers provided estimates of average annual water supplies that can be made available as Refuge based on modeled project supplies. The average water supply across all project years is 360 AF.

We apply Delta Export unit values from the WSIP Technical Reference.⁴ Without this project in place, wildlife refuges alternative supply source is most likely to be purchasing water on the market that is exported through the Delta. Based on the average annual water supplies in each year type and the historical occurrence of each year type, we arrive at a total expected volume of water for each year type. Based on these volumes of total water supply, weights are created for each year type. The project would provide 51% of total refuge supplies in dry years, 24% in below normal years, and 25% in critical years.

Table 2. Unit Value Weights

	Average annual refuge supplies by year type (TAF)	Year type occurrence	Total expected volume of water (TAF)	Unit value weights based on total volume
Wet	0	0.32	0	0%
Above Normal	0	0.15	0	0%
Below Normal	0.51	0.17	0.09	24%
Dry	0.82	0.22	0.18	51%
Critical	0.6	0.15	0.09	25%

Creating a weighted average of unit values yields an average alternative cost of \$300 in 2030 and \$760 in 2045, both in 2015 dollars. To calculate the net present value of the total benefits, we multiply the average

⁴ California Water Commission. Technical Reference. November 2016. <https://cwc.ca.gov/-/media/CWC-Website/Files/Documents/2017/WSIP/TechnicalReference.pdf>

supply of 360 AF by the weighted cost in each year of the project life, interpolating between 2030 and 2045, and take the present value of the stream of benefits. The total net present value is \$5.9 million in 2015 dollars, or \$6.4 million in in 2018 dollars.⁵

⁵ NPV is inflated to 2018 dollars using California Department of Finance Consumer price index. <http://www.dof.ca.gov/Forecasting/Economics/Indicators/Inflation/>

RE: Estimate of Benefits and Assumptions for the Wetland Ecosystem Benefit of the Kern Fan Groundwater Storage Project for the Water Infrastructure Improvement for the Nation Program (WIIN)

Introduction

This supplemental memo outlines the data, assumptions, and methodological approaches for calculating the wetland ecosystem benefit of Irvine Ranch Water District's (IRWD) and Rosedale Rio Bravo Water Storage District's (Rosedale) proposed Kern Fan Groundwater Storage Project (Storage Project) under two scenarios. Both estimates use an alternative cost approach, which values the wetlands at the amount that it would cost to construct an alternative project that provides the same ecosystem benefit as the Storage Project.

Overview

The Kern Fan Integrated Groundwater Storage Project (Project) will provide ecosystem benefits and other public and non-public benefits by recharging and storing up to 100,000 acre-feet (AF) of unallocated State Water Project (SWP) Article 21 water, unallocated Kern River floodwater, and other available water supplies, as available, in the Kern County groundwater basin. Water would be stored for subsequent extraction and recovery to offset surface water demands during periods of need. The project will provide a variety of benefits, including water supply, groundwater improvement, ecosystem, agriculture, and emergency response benefits, estimates of which have been detailed in previous memos based on project information provided by IRWD, Rosedale, Cramer Fish Sciences and MBK Engineers.

This memo focuses on the wetland ecosystem benefit, providing detailed assumptions used by M.Cubed to estimate benefits under (1) a long-term acquisition scenario, and (2) a temporary acquisition scenario. Under the long-term scenario, the Project uses a long-term permanent easement to create a wetlands in wet years only, mimicking the pattern of wetlands creation that is projected to take place with the Storage Project over a total of 33 months. An alternative approach is to assume that wetlands creation can take place at any time, not just in wet years, as long as the period of inundation is equivalent to that under the Storage Project. Under this temporary scenario, the Project leases agricultural land and creates a wetlands during the three winter months over 11 years, or a total wetlands creation of 33 months. Estimates of the net present value (NPV) of total benefits under both of these scenarios in 2018 dollars are outlined in Table 1.

Table 1. Summary of Benefits for Two Wetland Benefit Scenarios

Scenario	NPV of Benefits (2.875%)
Long-term Acquisition	\$162.6
Temporary Acquisition	\$203.7

Project benefits are expected to begin in 2026 and continue throughout the 50-year life of the project, through 2075 in the case of the long-term scenario, and 11 years, in the case of the temporary scenario. We calculate net present value at the project start in 2026. The net present value calculation uses a discount rate of 2.875%, which is the rate Federal agencies use in water resources planning.¹ All cost estimates are presented in 2018 dollars.

Throughout this analysis we rely on work already produced for the Kern Fan Project to apply for funding under California’s Water Storage Investment Program (WSIP).

Scenario Details

The Project will provide ecosystem benefits by creating wetlands habitat for migratory birds during the years that it takes and recharges into groundwater aquifers Article 21 water and other excess flows. During those years, the 1,280 acres that comprise the project will be inundated with water to percolate into the groundwater basin. The inundated lands will provide temporary habitat to migratory bird species along the Pacific Flyway.

In the original analysis undertaken in support of the WSIP funding process, only Article 21 water was considered in the calculation of benefits. Considering only Article 21 water, based on historical hydrologic conditions, we expect recharge to take place in 21 months over the 50 year life of the project.² Additional modelling was carried out to consider the impact of added non-Article 21 water sources, and a hydrologic analysis found that tapping these sources would result in recharge occurring in an extra 12 months over the project lifetime, or a total of 33 months. For the purposes of this analysis, we assume that the project takes advantage of all available water recharge supplies, and uses the 33 months of recharge. During these 33 months a volume of approximately 461,000 AF would be spread over the 1,280 acres to provide wetland habitat.

Long-Term Scenario--Under the permanent scenario, we use an alternative cost approach for a project that would create equivalent wetland habitat in Kern County. Under this scenario, we assume the Project would acquire a permanent easement on 1,280 acres, build the infrastructure to inundate the property, and provide the same volume of water to flood the fields in wet years for 33 months out of the project life.

To estimate the cost of acquiring a long-term permanent easement on the 1,280 acres of land suitable for inundation we use easement costs from the Project Sponsors’ project cost estimates developed in funding applications of \$11,100 in 2018 dollars.³ The alternative source of water for providing temporary wetland habitat in the area is Delta export water, so we estimate construction costs to include a connection to the

¹ U.S. Bureau of Reclamation, “Change in Discount Rate for Water Resources Planning,” <https://www.federalregister.gov/documents/2018/12/18/2018-27331/change-in-discount-rate-for-water-resources-planning>, December 18, 2018.

² Based on hydrologic analysis from MBK Engineers.

³ Note that the cost of purchasing land outright is estimated at \$24,000 per acre.

California Aqueduct, the only way to obtain water transfers originating north of the Delta. We estimate wetland construction costs to include earthwork and interbasin structures, lift stations, conveyance infrastructure, and a canal connection to the California Aqueduct, as well as the canal easements, compliance costs, and habitat credits necessary to carry out construction. Based on the Project's construction cost estimates the cost of constructing a wetlands project is \$52.7 million in 2018 dollars. We assume that the entire 461,000 to 465,000 AF of water will be applied to the wetlands over the 50 year easement. For the purpose of estimating a stream of costs, we use an expected annual application of 9,200 to 9,300 AF of water over the 50 years of potential wetland creation. Since the project would only create wetlands in wet years, we use the Delta Export unit value estimates for wet years provided in the WSIP Technical Guidance, which ranges from \$220 in 2030 to \$450 in 2045 in 2018 dollars, as well as a per AF conveyance cost of \$19. We interpolate between these values and leave prices beyond 2045 set at \$450 to be conservative. Since we do not know the exact timing of wet years over the project lifetime, we use the expected value of flood water volumes to create a stream of expected costs over the 50-year project lifetime. Taking the net present value of this stream of costs results in a total alternative cost of **\$162.6 million**.

Temporary Scenario— Under the Temporary scenario, we use an alternative cost approach for a project that would provide equivalent wetland habitat in Kern County, assuming that habitat provision could happen in any 33 months with equal ecosystem benefit, not just in wet years when the Storage Project would take flood flows. Under this scenario, we assume the Project would acquire a temporary easement on 1,280 acres, build the infrastructure to inundate the property over the 3 winter months of the first 11 years of the project, and provide the same volume of water to flood the fields for these 33 months. We assume wetland creation would only occur in winter months, with benefits spanning winter and spring months when stopovers on the Pacific Flyway are of greatest use, so that the benefits to migrating waterfowl are comparable to the benefits created under the Storage Project.

To estimate the cost of acquiring a temporary easement on the 1,280 acres of land suitable for inundation we use an estimate of the price of an agricultural lease in Kern County. The Project Sponsors' assessors confirmed that the only land available within a reasonable 5-10 mile distance of the California Aqueduct is agricultural land for lease for an average of \$310 per acre in 2018 dollars. The alternative source of water for providing temporary wetland habitat in the area is Delta export water, so we estimate construction costs in the same way as for the permanent scenario, including a connection to the California Aqueduct. Construction costs are the same as the permanent scenario, \$52.7 million in 2018 dollars. However, the temporary scenario includes an additional cost in the 11th year of the project to remove the wetland construction and return the land to its original state. This includes removal of embankments, walls and interbasin structures, with a total cost of \$799,000 in 2018 dollars. We assume that the entire 461,000 AF will be applied to the wetlands over the 11 years, or an average of 42,000 AF annually. We use the Delta Export unit value estimates from the WSIP Technical Guidance, weighted by the occurrence rate of each type of hydrologic year, since there is no way to know what type of water years will occur over the 11 years of wetland creation. These weighted unit values range from \$290 in 2030 to \$690 in 2045 in 2018 dollars, as well as a per AF conveyance cost of \$19. We interpolate between these values to arrive at price estimates over the 11 years of wetland creation. Taking the net present value of this stream of costs over 11 years results in a total alternative cost of **\$203.6 million**.

Scenario Selection

While we did examine both a long-term easement and a temporary easement scenario in order to explore all potential alternatives, we determine that a short-term easement or land lease for an alternative wetland creation project would not be appropriate. Because creating an inundated wetlands would

require significant construction and changes to land use to create a containment basin or a free-standing wetland, it would not be appropriate to lease existing productive agricultural land. Orchards and irrigated agriculture using water-efficient modern irrigation methods are not appropriate for temporary wetlands creation on the scale of three or more months, nor are petroleum-production lands, because of existing infrastructure. Considering that all of the land within a reasonable 5 to 10 mile distance of the California Aqueduct is occupied as productive agriculture, the temporary scenario presents a barrier. Because the long-term scenario is also the least cost between the two alternatives, we determine the long-term scenario to be the most appropriate in calculating the benefit cost ratio of the Project.

Other alternatives explored included using existing recharge basins rather than leasing or procuring an easement to create wetlands. However, existing recharge basins are already in use during winter months. The wetland benefit is particular to winter and spring months when migratory birds would be present, and existing water banking recharge basins would typically be in use during the remainder of the year, recharging sources of water other than excess flows during years of normal hydrology. During dry and critical dry years when surface water is reduced, water banking entities are typically recovering previously stored water. Operationally, when water banking entities are recovering water through extraction wells they would not also be delivering water for recharge. They would use the surface recharge water in-lieu of groundwater. During dry years, the recharge basins would typically remain dry and used for livestock grazing.

RE: Estimate of Benefits from the Kern Fan Groundwater Storage Project for the Water Infrastructure Improvement for the Nation Program (WIIN)

Introduction

This technical memo outlines the data and methodological approach for calculating the economic benefits of Irvine Ranch Water District's (IRWD) and Rosedale Rio Bravo Water Storage District's (Rosedale) proposed Kern Fan Groundwater Storage Project in support of a feasibility study under the Water Infrastructure Improvement for the Nation Program (WIIN).

Overview

The Kern Fan Integrated Groundwater Storage Project (Project) will provide ecosystem benefits for the Delta and its tributaries and other public and non-public benefits by recharging and storing up to 100,000 acre-feet (AF) of unallocated State Water Project (SWP) Article 21 water, unallocated Kern River floodwater, and other water, as available, in the Kern County groundwater basin. Water would be stored for subsequent extraction and recovery to offset surface water demands during periods of need. Deliveries of unallocated Article 21 water would be made on behalf of Irvine Ranch Water District (IRWD) as a landowner in Dudley Ridge Water District (DRWD) and Rosedale as a sub-unit of the Kern County Water Agency. During droughts or times of need when surface supplies are reduced, stored groundwater will be recovered from the Project with up to 12 new extraction wells and conveyed to points of use in DRWD, IRWD and Rosedale's service areas. Approximately 25% of the stored Article 21 water would be held as SWP system water that would be used for ecosystem benefit purposes in the Delta. This 25% of the water would be made available for ecosystem benefits through operational exchanges, which would be facilitated through a Coordinated Operating Agreement that would be executed between the project partners and Department of Water Resources (DWR). The project will provide a variety of benefits, including water supply, groundwater improvement, ecosystem, agriculture, and emergency response benefits. Based on project information provided by IRWD, Rosedale, Cramer Fish Sciences and MBK Engineers, M.Cubed completed estimates of the economic benefits in these five benefit categories. Estimates of the net present value (NPV) of total benefits in 2018 dollars are outlined in Table 1.

Table 1. Summary of Benefit Estimates

Type of Benefit	NPV of Benefits (2.875%)
Water Supply Benefits—M&I	\$49.5
Water Supply Benefits—Agriculture	\$77.8
Water Supply Benefits--Groundwater	\$9.1
Environmental Benefits—Fish species recovery	\$37.5
Environmental Benefits—Incidental Wetland Habitat	\$162.6
Emergency Response—Extended drought	\$18.1
Emergency Response—Delta failure	\$29.6
Agricultural Benefits	\$25.8
Total Benefits	\$410.0

Project benefits are expected to begin in 2026 and continue throughout the 50-year life of the project, through 2075. We calculate net present value at the project start in 2026. The net present value calculation uses a discount rate of 2.875%, which is the rate Federal agencies use in water resources planning.¹

Throughout this analysis we rely on work already produced for the Kern Fan Project to apply for funding under California’s Water Storage Investment Program (WSIP).

Benefits

Water Supply--Municipal and Industrial

Municipal and Industrial (M&I) Water Supply benefits are non-public benefits that will accrue to IRWD, Rosedale, and Dudley Ridge, and their service area customers. According to modeling results from MBK Engineers, considering only Article 21 water supplies, the project will provide on an average annual basis 2,700 acre-feet of water by 2030 and 3,000 acre-feet by 2070 in non-public water supply benefits. However, Rosedale estimates that an additional 9,415 AF will be available on average annually from non-Article 21 water sources including other State Water Project Table A, Kern River high flow, Kern River flood, and Friant 215 supplies, of which an additional 2,900 acre-feet of water will be available annually for non-public water supply benefit. According to historical supply sources for Rosedale and IRWD, on average there would be approximately 7,468 AF of water available to agriculture,² and approximately 1,947 AF of water available to IRWD.³ To be conservative we assume that this supply remains constant over time, rather than increasing in the same way that Article 21 water is projected to do. Approximately three-quarters of the total water supply will be available to Rosedale and Dudley Ridge for agricultural use, and the remaining one-quarter will be available to IRWD under both future conditions.

¹ U.S. Bureau of Reclamation, “Change in Discount Rate for Water Resources Planning,” <https://www.federalregister.gov/documents/2018/12/18/2018-27331/change-in-discount-rate-for-water-resources-planning>, December 18, 2018.

² Based on deliveries to the smaller 300-acre Kern-Tulare and Rag Gulch water storage facilities operated by RRBWSD from 2004 to 2017, weighted by probability of water-year type.

³ For 2010 to 2017, weighted average by water year type, and only in wet years for IRWD water.

We use the alternative cost approach to estimate the water supply benefits of the project. The water supply benefit is divided between agricultural (75%) and urban uses (25%), which face different alternative costs of water.

For urban municipal and industrial uses by IRWD, the alternative supply cost is the Tier 1 untreated rate from Metropolitan Water District of Southern California (MWDSC), which was \$676 per AF in 2015. We escalate this rate over time using MWDSC's forecast of Tier 1 prices as found in their Ten-Year Financial Forecast provided at a February 9, 2016 MWDSC Board Meeting.⁴ According to the forecast of Full Service Untreated Tier 1 water, prices are projected to increase by an average of 5.6% from 2016 to 2026. Over the same period, average CPI inflation is projected to be 2.3%, resulting in an average real price increase of 3.3%. We apply this rate of increase to MWDSC Tier 1 rates over the life of the project. We consider documentation provided by MWDSC on their expected price increases to be sufficient rationale and documentation of urban water price escalation. We also apply conveyance costs using data provided by Dudley Ridge, which includes monthly conveyance costs from 2001 to 2017.⁵ Conveyance costs average \$18.67 per AF in 2018 dollars.

Applying the 2.875% discount rate to the stream of alternative water supply costs, we arrive at the total net present value of non-public water supply benefits of **\$49.5 million**.

Water Supply--Groundwater

To evaluate the groundwater benefit, we use the alternative cost approach to estimate how much it would cost to purchase the same volume of water for groundwater recharge in Kern County as that provided by the project.

According to groundwater policy in Kern County, a portion of banked groundwater is not recovered by the banking entity and remains in the ground to bolster local groundwater levels. For this project groundwater basin leave-behind percentages vary depending on the water supply account--9% of water in the urban account and 4% of water in the agricultural account will be left to help recharge local basins, according to groundwater modeling assumptions used by MBK Engineers. These numbers are also consistent with an existing Memorandum of Understanding (MOU) between Rosedale and other Kern Fan banking entities. For the environmental account, we apply an average of these two rates, or 6.5%. Based on these values, we find a weighted average leave-behind rate of 6.6% in 2030 and 6.5% in 2070 and use these shares to calculate the total groundwater level benefit.

For the purpose of recharging groundwater, we consider the alternative cost to be the cost of purchasing water through a water market, likely in northern California, that would be exported through the Sacramento-San Joaquin Delta. For an estimate of average costs of purchasing Delta export water on the water market, we use unit values developed by the California Water Commission in their Water Storage Investment Program Technical Reference.⁶ These unit values were developed from a statistical analysis based on water transfer prices from 1992 to 2015, the Statewide Agricultural Production Model (SWAP), and assumptions regarding groundwater sustainability requirements in the state by 2045. These unit values were developed for various water year types (wet, above normal, below normal, dry, and critical) for 2030 and 2045, the year it is assumed that groundwater basins will reach sustainable levels. We weight Delta Export costs according to historic water year type frequency according to the San Joaquin River Water Year Index⁷ to arrive at benchmark values for 2030 and 2045. As in the Non-Public Water Supply benefit above, we also added SWP conveyance costs to Delta Export costs. We use the same conveyance

⁴ MWDSC Board meeting minutes with forecast summary included in the Appeal Supplement.

⁵ Data from Dudley Ridge WD included the Appeal Supplement.

⁶ California Water Commission. Technical Reference. November 2016. <https://cwc.ca.gov/-/media/CWC-Website/Files/Documents/2017/WSIP/TechnicalReference.pdf>

⁷ California Department of Water Resources. <http://cdec.water.ca.gov/reportapp/javareports?name=WSIHIST>

cost of \$18.67 in 2018 dollars based on 2001-2017 conveyance cost data provided by Dudley Ridge. Interpolating between 2030 and 2045 values and taking the sum across all project years, we find a net present value of **\$9.1 million** at the project start, in 2018 dollars.

Water Supply--Agricultural

We use the alternative cost approach to estimate the water supply benefits of the project. The water supply benefit is divided between agricultural (75%) and urban uses (25%), which face different alternative costs of water. All of Rosedale's water supply is used for agriculture, and half of IRWD's water supply goes toward agricultural end uses in Kern County.

For agricultural water use, we use the Delta Export unit value described in the groundwater benefit section above as the value of an alternative water supply for Rosedale and Dudley Ridge. Delta export values are provided for 2030 and 2045, which we re-weight according to the water year types during which IRWD and Rosedale are expected to recover stored groundwater according to MBK Engineers. Since IRWD and Rosedale are projected to accrue water supplies in different water year types (with Rosedale drawing on their supplies mainly in dry and critically dry years, while IRWD's supply benefits occur in above normal through critically dry years) two different water values are required—one weighted for IRWD's supply and one weighted for Rosedale's supply. These weights are available for 2030 and 2070 based on MBK's Engineering analysis. We therefore use water cost anchor points of 2030, 2045, and 2070—2030 unit values weighted at 2030 recovery levels, 2045 unit values weighted at 2030 recovery levels and 2045 unit values weighted at 2070 recovery levels. We interpolate between these points and extrapolate to find unit values for 2026 to 2075. These unit values range from \$345 per AF for IRWD, and \$353 per AF for Rosedale in 2030 to \$917 per AF for IRWD and \$944 per AF for Rosedale in 2045 in 2018 dollars. We also apply conveyance costs using data provided by Dudley Ridge, which includes monthly conveyance costs from 2001 to 2017.⁸ Conveyance costs average \$18.67 per AF in 2018 dollars.

Applying the 2.875% discount rate to the stream of alternative water supply costs, we arrive at the total net present value of non-public water supply benefits of **\$77.8 million**.

Environmental—Fish Species Recovery

We consider two approaches to evaluating the environmental benefit from salmon conservation—the willingness to pay approach, based on a per fish benefit value for two runs of Chinook salmon and the alternative cost approach. We describe the willingness to pay approach below but ultimately use the alternative cost approach as our final estimate of project benefits.

The project will create increased environmental flows in dry and critical years by offsetting State Water Project Table A water demands and making that water available for instream flows from Lake Oroville, along the Feather and Sacramento Rivers, and in the Delta estuary. Based on water modelling carried out by MBK Engineers, Cramer Fish Sciences recommended pulse flows on the Feather River to maximize benefits to Winter and Spring run Chinook Salmon, and Steelhead Trout.

Cramer Fish Sciences modeled the number of fish that would be restored in the 2030 and 2070 future conditions based on the project using Article 21 water supplies only. No further analysis is available on how additional non-Article 21 water would impact fish populations. Based on Article-21 water only, we take the annual expected number of additional winter-run and spring-run Chinook for 2030 and 2070, and interpolate between the two points, and extrapolate backwards to 2026.

The WSIP Technical Reference recommends a benefit of \$100,000 per fish per year for winter and spring-run Chinook.⁹ In order to arrive at that estimate, the California Water Commission reviewed numerous

⁸ Data from Dudley Ridge WD included the Appeal Supplement.

⁹ California Water Commission. Technical Reference. November 2016. <https://cwc.ca.gov/-/media/CWC-Website/Files/Documents/2017/WSIP/TechnicalReference.pdf>

contingent valuation studies for West Coast salmon and steelhead trout, and ultimately drew on two studies. The first is a willingness to pay survey of 11.9 million California households, that found a median willingness to pay of \$80,000 per fish for salmon restoration.¹⁰ In addition, a study by the National Oceanic and Atmospheric Administration estimated the cost of restoring Central Valley Chinook salmon and steelhead at \$58,000 to \$120,000 per adult fish.¹¹ The California Water Commission found that these two studies provide a reasonably consistent basis for estimating the value of restoration for these fish species, recommending a value of \$100,000 per fish per year. We apply this value to the stream of future additional Chinook to calculate a net present value of \$59.1 million. However, this is only a partial benefit, based on a fraction of the total project supply.

This analysis did not quantify benefits separately to steelhead trout or green sturgeon due to lack of sufficient information, however, Cramer Fish Sciences found that there would be additional benefit to both species, both of which are considered highest priority by the California Department of Fish and Wildlife. Since this analysis ultimately uses the alternative cost of procuring environmental water, rather than the willingness to pay approach, impacts to these individual species are not evaluated. However it should be noted that they would also benefit from the project.

To calculate the final environmental benefit of Salmon recovery we rely on the alternative cost approach. This approach is based on the cost of procuring a similar volume of water in dry and critical years for environmental flows. We again rely on unit values for Sacramento Valley agriculture developed by the California Water Commission in their WSIP Technical Reference as the alternative water source for environmental pulse flows, weighted by the years in which pulse flows would be available from the project. Unit values were derived in the same manner as for Delta Exports, described above in the section *Public Benefits—Agricultural Water Supply*, for the Sacramento Valley, which typically has more water resources available and therefore lower market prices.

To provide these flows in April and May of a Dry or Critically Dry year with a similar amount of certainty as the Kern Fan Storage Project would provide, an option agreement would need to be in place with suppliers in the Sacramento Valley. It is currently uncertain whether 18,000 acre-feet of water would be available in any given critically dry year. In addition, there is an issue of timing, since the water year type is not known with any certainty until March,¹² but pulse flows would provide the greatest benefit in April or May. Meanwhile farmers in the Sacramento Valley who would be making water available to transfer through fallowing would need to make their planting decisions in February and would incur losses if they make the decision to instead fallow land in the spring. Farmers would need to be compensated for this uncertainty in their planting decisions or would need to plant lower-value crops that require less initial investment. In fact, one of the main benefits of a storage project like the Kern Fan Project is that it provides certainty that water would be available for the environment in dry and critical years, and at any time in the spring when it would be most beneficial.

Options have been used for larger-scale Sacramento Valley water transfers at least four times—1995, 2003, 2005, and 2008. Without an option agreement already in place, there would not be sufficient time to reach an agreement in March, or if there was, there is a real possibility that farmers would need to be compensated for sunk costs in their initial planting. The options provide a level of certainty that water supply can be called every year on relatively short notice, given that the conditions driving that decision

cannot be known until shortly before the call is made. Options payments take these uncertainties into account.

We rely on several historical options contracts in the Sacramento Valley to estimate an appropriate option payment. There are four well-documented option contracts that have been used to account for the uncertainty of water transfers from the Sacramento Valley since 1995. For all of these transfers the option payment ranged from \$3.50 to \$10.00 per acre-foot paid every year whether the water was called or not, for the option of calling on water by February 15 of each year, before farmers have made investments in their fields.¹³ The two more recent transfers, which took place in 2005 and 2008 include an additional option payment of \$20.00 and \$40.00 per acre-foot respectively, which allows the buyer to extend the call date from February 15 to May 2. This extra payment compensates farmers for any losses from initial planting. Since pulse flows provided by this project would be made available in April and May, this extension would be necessary to create an equal amount of certainty that flows would actually be available. We therefore use an average of the \$30.00 option from the Glenn-Colusa Irrigation District, *et al*-Metropolitan Water District of Southern California transfer in 2005 and the \$50.00 option from the Butte Water District-SDCWA transfer in the 2008 contract, both converted to 2018 dollars, or \$50.48 as the appropriate option value. We apply this payment to the full pulse flow volume for every year, independent of water year type, since it would have to be paid for the life of the project to deliver an equivalent benefit. We use the Sacramento Valley unit values from the TR, weighted for the hydrologic year types (dry and critical) when environmental pulses are expected to take place as the actual cost of transferred water. Using the alternative cost approach with the fully supply of Article 21 and non-Article 21 water, we find a benefit of **\$37.5 million** in 2018 dollars.

When two valuation options are possible, the approach with the lesser benefit value should be used. However, since the willingness to pay analysis is incomplete, we use the alternative cost approach. However, it should also be noted that when the willingness to pay approach and the alternative cost approach are both applied to Article 21 water only, the alternative cost approach arrives as the lesser benefit value and is still the most suitable approach.

Environmental—Incidental Wetland Habitat

The water storage project will provide incidental wetland habitat for migratory birds during the years that the Kern Fan Project takes and recharges water into storage. During those years, the 1,280 acres that comprise the project will be inundated with water to percolate into the groundwater basin. The ponds will provide temporary habitat to migratory bird species along the Pacific Flyway.

To estimate the benefits associated with this habitat, we used the alternative cost approach.

In an alternative approach scenario IRWD would purchase the land to create an equivalent amount of wetlands over a similar period as those created by the project. To estimate the land value, we use the cost of a permanent easement rather than outright purchase. Based on the Project cost estimates the cost of a long-term easement, suitable for constructing water conveyance facilities on would cost \$10,750 per acre in 2017 dollars, or \$11,133 in 2018 dollars. We use the same costs to move water from the aqueduct as in the above approach, which includes a canal connection to the California Aqueduct, a conveyance canal to the site, canal siphons, and lift stations in addition to significant earthwork and interbasin structures to keep water in the basins. We assume that the Kern Fan project would be farther from the California Aqueduct than any other option (approximately 10 miles as identified in the Application), so the expected cost would be for a canal of half the length used in project cost estimates

¹³ In 1995, the State Drought Water Bank paid water districts \$3.50 per AF to call water at \$40 per AF. In 2003, MWDSC established a transfer option agreement with Glenn-Colusa Irrigation District, of which about half of the 60,000 AF under option was called. In 2005 MWDSC signed a contract with Glenn-Colusa ID for just over 100,000 af. In 2008, San Diego County Water Agency agreed to an option with Butte Water District and Sutter Extension Water District. The documentation for the latter three agreements are included in the Appeal Supplement.

and do not include any costs associated with recharge and recovery. We also include the costs of restoring the land to its pre-wetland condition at the end of the project, based on a subset of costs from the project budget. For this approach, since the alternative project would only take excess water in wet years, we use the Delta Export unit value for wet years provided in the WSIP TR, which ranges from \$204 in 2030 to \$414 in 2045. We add in the conveyance cost from the period from 2001 to 2017, \$17.10 per acre-foot. We interpolate between these values and leave prices beyond 2045 at \$414 per AF to be conservative. Taking the net present value of this stream of benefits results in a total benefit of **\$162.6 million** at the project start in 2018 dollars.

Emergency Response—Extended Drought

A major benefit of the project is that it provides water to IRWD, Rosedale, and Dudley Ridge in the event of extreme drought, when other water resources are at their most expensive. Groundwater stored as part of the project will be available to call on during a drought emergency or as an alternative supply in the case of a local supply outage. Here we use the alternative cost approach. We also apply the definition of an emergency drought as a critical year that occurs in the third or later year of consecutive dry and critically dry years.

Water modeling results carried out by MBK Engineers estimates a drought emergency supply availability of 4,750 in both the 2030 and 2070 future conditions. However, these estimates consider only Article 21 water and no other water sources. Water modeling is not available for the full supply of project water, so we consider these volumes to be conservative estimates of the actual drought benefit. The actual benefit is likely higher than these estimates.

Using these volumes, interpolating between them, and extrapolating to the beginning of the project in 2026, we arrive at the volume of water supply available for emergency response in each year of the project life.

Alternative costs are based on the lowest cost alternative agricultural water for Rosedale and Dudley Ridge, and urban water for IRWD. Under conditions of extended drought we rely on data provided by Dudley Ridge on the water offers it received from 2014 through 2016, as a documented source of the price that agricultural users in Kern County are willing to accept for water during an extended drought period.¹⁴ There are only two cases of extended drought in the hydrologic record-- 1987-1992 drought and the recent 2012-2016 drought. Since water transfer data is only available for the most recent drought, we consider that 21 observations over three years at the end of the worst drought in California history to be sufficient basis for a drought emergency benefit. The median offer in 2018 dollars is \$690 per acre-foot.¹⁵ We include the SWP conveyance cost of \$17.10 per acre-foot based on 2001-2017 monthly data from Dudley Ridge.

For the urban supply, the alternative source is imported water from MWDSC. However, in addition to the normal Tier 1 rate of \$676 per acre-foot, IRWD would have to pay a \$1,480 per acre-foot penalty for exceeding their allocation in an emergency scenario, bringing the total cost to \$2,156 per acre-foot. As outlined above in the section on Water Supply Benefits, in this analysis we use 10-year projected escalation of Metropolitan's Tier 1 rate, net of CPI inflation over the same period, based on price projections provided by Metropolitan to its board in 2016. We apply this escalation rate, 3.3% to the Tier 1 rate only, and do not escalate the \$1,480 penalty or any other additional charges to the Metropolitan rate. To be conservative we apply this 2015 rate to emergency water supplies for years from the start of the project through 2030.

¹⁴ Data from Dudley Ridge available in "Other Supporting Documentation Uploaded" section of the Appeal letter.

¹⁵ As a confirmation, Buena Vista Water Storage District also held an auction in which the median value paid by buyers was \$1,200 per AF. Because these are cleared market prices rather than offers, we did not average the two data sources. The BVWSD data is included in the Appeal Supplement.

Applying the agricultural emergency supply rate to the 75% of the emergency water supply available to Rosedale and Dudley Ridge and the urban emergency rate to the 25% of the emergency water supply available to IRWD, we arrive at annual emergency supply alternative costs. However, according to historical hydrologic year data provided by MBK Engineers, a critical year in the third year or later of a multi-year drought has only occurred in 6 of the 82 years on record-- a 7% probability of occurrence. We apply this probability to the entire stream of alternative costs and take the net present value at the project start to arrive at a benefit of **\$18.1 million**.

Emergency Response—Delta Failure

A separate emergency response benefit of the project is the emergency water supply it can provide in the event of a levee failure in the Delta that curtails State Water Project and Central Valley Project deliveries to the Central Valley and Southern California. We analyze this benefit using an alternative cost approach.

For this benefit, we assume that a Delta Failure occurs once, 30 years into the project operation period—2056 for this project. This is the recommended approach by the California Water Commission for valuing emergency response water supplies in their Technical Reference. According to the analysis carried out by MBK Engineers, according to historical hydrology, the project is likely to have 23,500 acre-feet of water available for emergency response after 30 years of operation. Again, these modeling results include only Article 21 water rather than the full project supply. These estimates therefore are conservative and the true benefit is likely to be greater.

In the event of interrupted flows through the Delta, IRWD's alternative supply will be water purchases from MWDSC. We therefore use MWDSC's Tier 1 rate of \$676 per acre-foot in addition to a \$2,960 penalty for water use over 115% of IRWD's allocation. In this analysis, as outlined in previous sections, we use an escalation factor based on Metropolitan's projected rates increases over a 10-year period, as presented to the MWDSC Board in 2016.¹⁶ To be consistent with other benefits, we escalate only the Tier 1 rate at the projected rate increase based on MWDSC's estimates for 2016-2026. The \$2,960 penalty and all other charges are not escalated. To be conservative, we use current water costs in the year 2030 and escalate costs after that point. As with other benefits, we apply the urban rate to the approximately 25% of the emergency supply that would go to urban users.

Because normal agricultural water deliveries through the Delta would not be available in this scenario, we use a different approach to value the agricultural benefit. As a unit value, we use the median offer price provided by Dudley Ridge for the 2014-2016 period of \$632 per acre-foot on the presumption that a Delta emergency would be interpreted as equivalent to an extended drought due to the uncertainty about when exports would be resumed. Agricultural users have demonstrated that they are willing to pay this amount in times of a "normal" extended drought. We believe that a Delta outage, however, will represent unprecedented shortage conditions south of the Delta. Under such conditions, the only alternative supply available to agricultural users is groundwater. Presumably pumps would be turned on "24/7" to replace lost surface supplies in the San Joaquin Valley. To adjust for the overdraft of groundwater during an unprecedented drought we assume that under the Sustainable Groundwater Management Act, which requires all groundwater basins to come to sustainable levels by 2040, users would be required to recharge some portion of the overdraft in subsequent years. To account for this cost, we add to the agricultural value 50% of the average Delta Export unit value to purchase replacement water in subsequent years. While we do not have any certainty about what this recharge requirement will be in the future, we do know that the actual value of water under these emergency conditions will be greater than those for a normal drought period, that agricultural users in the Central Valley rely heavily on groundwater in times of project supply shortages, and that SGMA will require groundwater basins to reach sustainable yields by the time we assume the Delta Outage occurs. Therefore, some assumption is necessary. Because this type of emergency is unprecedented in California it is impossible to document

¹⁶ Summary forecast included in Appeal Supplement

actual costs or demonstrate actual willingness to pay under similar conditions. Therefore, we believe that the value in an extended drought plus the 50% payback assumption is a conservative estimate of the true value of water under a Delta emergency.

Multiplying 25% of the 23,500 acre-feet emergency supply by the urban emergency water rate and 75% of the supply by the agricultural rate in 2056, we arrive at a total benefit estimate. The net present value of this benefit in 2026 is **\$29.6 million**.

Agricultural Impact

The Kern Fan Storage Project provides a greater degree of reliability for agricultural water supply, which creates benefits to local agriculture that go beyond the value of the water supply itself. According to Rosedale Rio Bravo Water Storage District the Kern Fan project would prevent approximately 600 acres of field crops from being fallowed in critically dry years when supplies are low. With increased reliability, they estimate that this acreage could instead be converted to higher value permanent crops, such as fruit or nut trees. While the value of agricultural water to the existing mix of crops is already included under the calculation of agricultural water supply benefit, the impact of crop conversion is a separate benefit.

To estimate the effects of crop conversion we use IMPLAN data for Kern County. IMPLAN is an input-output modeling software that allows users to estimate how economic changes in particular sectors impact the local economy. IMPLAN is an industry standard in modeling local economic impacts.

We first gathered agricultural data from the Kern County Department of Agriculture and UC Davis Agricultural Extension's Cost and Return Studies. Using these data we estimate the per acre impact to agricultural output from a 600 acre increase in fruit and nut crops and a 600 acre decrease in field crops. Cotton accounts for the largest share of field crops both in terms of acreage and income. We therefore assume that cotton is the most likely field crop to be fallowed during drought years. We also include an assumption that the cotton would be fallowed only in critically dry years, which occur approximately 20% of the time, according to historic water year type data for the San Joaquin River. Permanent tree crops would add economic benefits in every year. We use the overall output value for these two crop categories as an input into the IMPLAN model. Based on this scenario, IMPLAN estimates direct impacts of crop conversion at \$872,000 per year in 2015 dollars on a value added basis. To be conservative we do not scale this number up over time. We use the future stream of these economic impacts to estimate an NPV of \$25.8 million over the life of the project in 2018 dollars.

Though not covered in this analysis, the expected crop conversion will also result in secondary economic impacts. Indirect and Induced Effects of the additional agricultural output account for the economic boost from the agricultural industry's increased purchase of goods and services from other local industries, and the impact on the local economy from an increase in household spending due to an increase in jobs, respectively. While we do not include these secondary impacts in this analysis, we estimate that the Indirect impacts would be approximately \$432,000 and Induced Impacts would be \$269,000 annually over the life of the project, based on IMPLAN modeling (both in 2015 dollars).
